

Problem 2

(a) nC_2 Am

(b) $n! \rightarrow n$ factorial Am.

(c)

(i) $\langle W-M-E-S \rangle \rightarrow$ cost is

$$W-M \rightarrow 1.1$$

$$M-E \rightarrow 1.4$$

$$E-S \rightarrow 0.5$$

$$\text{Total Cost} \rightarrow \underline{3.0} \text{ Am}$$

(ii) Neighbors of (WMES)

$$\rightarrow MWES \rightarrow 2.2$$

$$\rightarrow EMWS \rightarrow 3.2$$

$$\rightarrow SMEL \rightarrow 2.9$$

$$\rightarrow WEMS \rightarrow 2.9$$

$$\rightarrow WSEM \rightarrow 2.6$$

$$\rightarrow WMSE \rightarrow \underline{2.5} \text{ Am.}$$

(iii) Next state would be $\langle \underline{MWES} \rangle$, because it has least cost of all neighbors & we are using greedy hill climbing algorithm. Am

(iv) Possible successors of $\langle \underline{MWES} \rangle$:-

$$\rightarrow WMES \rightarrow 3.0$$

$$\rightarrow EWMS \rightarrow 2.6$$

$$\rightarrow SWEM \rightarrow 2.7$$

$$\rightarrow MEWS \rightarrow 2.7$$

$$\rightarrow MSEW \rightarrow 2$$

$$\rightarrow MWSE \rightarrow 2.3$$

\therefore we pick $\langle \underline{MSEW} \rangle$ as the next state because it has lowest cost.

Possible successors of $\langle MISEW \rangle$

$\rightarrow SMEW \rightarrow 2.9$

$\rightarrow ESMW \rightarrow 2.5$

$\rightarrow WSEM \rightarrow 2.6$

$\rightarrow MESW \rightarrow 2.6$

$\rightarrow MWES \rightarrow 2.2$

$\rightarrow MSWE \rightarrow 2.2$

\therefore , there are no states with a cost lower than the cost of $\langle \underline{MISEW} \rangle$. \therefore , $\langle \underline{MISEW} \rangle$ is the terminating state. Ans
